- III. CONCLUSION

Hands on session: first of all, data filtering

Gaussian Blurring

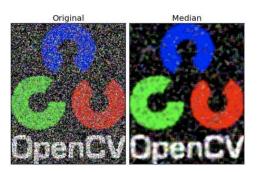

In this method, instead of a box filter, a Gaussian kernel is used. It is done with the function, cv.GaussianBlur(). We should specify the width and height of the kernel which should be positive and odd. We also should specify the standard deviation in the X and Y directions, sigmaX and sigmaY respectively. If only sigmaX is specified, sigmaY is taken as the same as sigmaX. If both are given as zeros, they are calculated from the kernel size. Gaussian blurring is highly effective in removing Gaussian noise from an image. The above code can be modified for Gaussian blurring:

 $blur = \underline{cv.GaussianBlur}(img,(5,5),0)$

Median Blurring

median = cv.medianBlur(img,5)

Hands on session: first of all, data filtering

autoencoder, Gaussian filter, Fourier transform, Median filter

1. Implement the code, compare the results obtained with the 2. Enhance the autoencoder: use the noisy images as inputs and original (noiseless) images as targets.

```
# Training the Autoencoder
for epoch in range(num epochs):
   for data in train loader:
       img, _ = data
       img = img.view(img.size(0), -1).to(device)
       noise = torch.randn(img.size()).to(device) * noise_factor
       noisy_img = img + noise
       noisy img = torch.clamp(noisy img, 0., 1.)
        # Forward pass
        output = model(noisy_img)
       loss = criterion(output, noisy img)
        # Backward pass and optimization
       optimizer.zero grad()
       loss.backward()
       optimizer.step()
    print(f'Epoch [{epoch+1}/{num epochs}], Loss: {loss.item():.4f}')
```

Fault diagnosis intuition

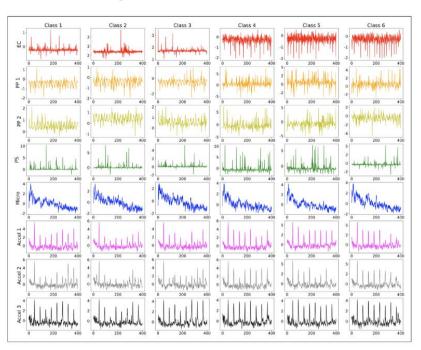

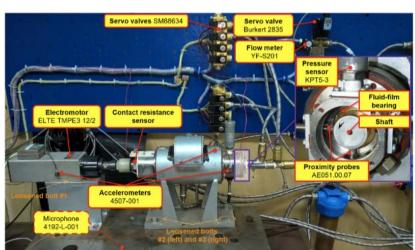

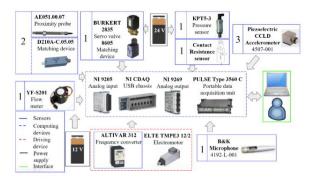

Figure 3. The measurement results in a form of training samples for all the classes of the test rig state: time series for the data obtained from the national instruments chassis (EC is electromotor current, PP 1, 2 are proximity probes, PS is pressure sensor) and the FFTs for the data obtained from the bruel&kjaer unit (micro is microphone, accel I–3 are accelerometers). Description for sensors is given in Table 1.

Fault diagnosis intuition

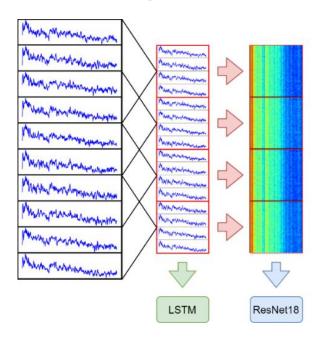

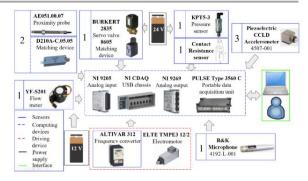

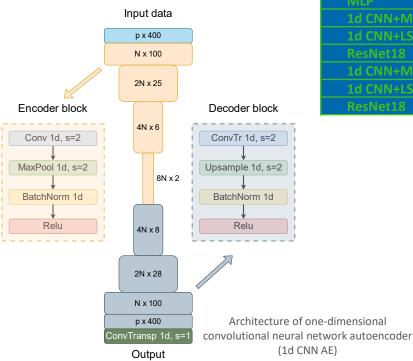

Table 3. The 6 classes classification results obtained using MLP and data from one of the sensors.

Sensor abbreviation	Train accuracy	Validation accuracy	Test accuracy
EC	0.478	0.324	0.373
PP I	0.37	0.375	0.359
PP 2	0.485	0.509	0.479
PS	0.492	0.403	0.544
Micro	0.929	0.458	0.719
Accel I	0.914	0.496	0.685

Abstract

Transformer architectures have widespread applications, particularly in Natural Language Processing and Computer Vision. Recently, Transformers have been employed in various aspects of time-series analysis. This tutorial provides an overview of the Transformer architecture, its applications, and a collection of examples from recent research in timeseries analysis. We delve into an explanation of the core components of the Transformer, including the self-attention mechanism, positional encoding, multi-head, and encoder/decoder. Several enhancements to the initial Transformer architecture are highlighted to tackle time-series tasks. The tutorial also provides best practices and techniques to overcome the challenge of effectively training Transformers for time-series analysis.

Transformers in Time-Series Analysis: A Tutorial

1-D Convolutional Neural Networks for Signal Processing Applications

Abstract-ID Convolutional Neural Networks (CNNs) have Fourier Transform (DFT) was applied, and then the two recently become the state-of-the-art technique for crucial signal transformed signals were concatenated into a matrix which can processing applications such as patient-specific ECG be fed to a conventional deep CNN. For electrocardiogram (ECG) classification, structural health monitoring, anomaly detection in classification and arrhythmia detection, the common approach is power electronics circuitry and motor-fault detection. This is an to use power- or log-spectrogram to convert each ECG beat to a expected outcome as there are numerous advantages of using an 2D image [12], [13]. However, there are certain drawbacks and adaptive and compact 1D CNN instead of a conventional (2D) deep counterparts. First of all, compact ID CNNs can be efficiently trained with a limited dataset of 1D signals while the 2D deep CNNs, besides requiring 1D to 2D data transformation, usually need datasets with massive size, e.g., in the "Big Data" scale in order to prevent the well-known "overfitting" problem. 1D CNNs can directly be applied to the raw signal (e.g., current, voltage, vibration, etc.) without requiring any pre- or postprocessing such as feature extraction, selection, dimension reduction, denoising, etc. Furthermore, due to the simple and compact configuration of such adaptive 1D CNNs that perform only linear 1D convolutions (scalar multiplications and additions), a real-time and low-cost hardware implementation is feasible. This paper reviews the major signal processing applications of compact 1D CNNs with a brief theoretical background. We will present their state-of-the-art performances and conclude with focusing on some major properties. Keywords - 1-D CNNs, Biomedical Signal Processing, SHM

I INTRODUCTION

Unlike the traditional Artificial Neural Networks (ANNs) Convolutional Neural Networks (CNNs) have the unique ability to fuse feature extraction and classification into a single learning body and thus eliminate the need for such fixed and hand-crafted features. Conventional deep CNNs (i.e. 2D CNNs) have been originally introduced to perform object recognition tasks for 2D signals such as images or video frames. They have recently become the de-facto standard for many Computer Vision and Pattern Recognition tasks within large data archives as they majority voting, etc. Another approach to tackle this problem is to achieved the state-of-the-art performances [1]-[3]. However, the use the majority of the dataset for training which may not be utilization of a conventional deep CNN for a 1-D signal feasible at all in many practical applications. In the study [26] processing application naturally requires a proper 1D to 2D conversion. For instance, recently, several researchers have Hence the assumption that such a large set of training data will be attempted to use deep CNNs for fault diagnosis of bearings [4]-[11]. For this purpose, they have used different conversion techniques to represent the ID vibration signals in 2D. The most compact 1D CNNs with few hidden layers/neurons, and their commonly used technique is to directly reshape the vibration applications to some major signal processing applications with the signal into an n×m matrix called "the vibration image" [9]. Another technique was used in [5] where two vibration signals were measured using two accelerometers. After that, Discrete detection/identification accuracy.

limitations of using such deep CNNs. To start with it is known that they pose a high computational complexity that requires special hardware especially for training. Hence, 2D CNNs are not suitable for real-time applications on mobile and low-power/lowmemory devices. Moreover, proper training of deep CNNs requires a very large training dataset in order to achieve a reasonable generalization capability. This may not be a viable option for many practical 1D signal applications where the labeled data is scarce. To address these drawbacks, compact 1D CNNs have been

recently developed to operate directly and more efficiently on 1D signals. They have achieved the state-of-the-art performance levels in several signal processing applications such as early arrhythmia detection in electrocardiogram (ECG) beats [15]-[17] on-site structural health monitoring [14], [18]-[22], motor fault detection [23] and real-time monitoring of high-power circuitry [24]. Additionally, two recent studies have utilized 1D CNNs for damage detection in bearings [25], [26]. However, in the latter study conducted by Zhang et al. [26], both single and ensemble of deep 1D CNN(s) were created to detect, localize, and quantify bearing faults. The deep configuration of 1D CNN used in this study consisted of 6 large convolutional layers followed by two fully connected layers. Other deep 1D CNN approaches have been recently followed by [27]-[29] for anomaly detection in ECG signals. These deep configurations share the common drawbacks of their 2D counterparts. For example, in [26], several "tricks" were used to improve the generalization performance of the deep CNN such as data augmentation, batch normalization, dropout, more than 96% of the total data is used to train the deep network available may hinder the usage of this method in practice. Therefore, in this study we shall draw the focus particularly on assumption that the labeled data is scarce and personalized or device-specific solutions are required to maximize the

Cloud of points

Cloud of points processing: PointNet

1. Point Feature Extraction

Each point p_i in the point cloud is represented as a vector $p_i = (x_i, y_i, z_i)$. The local features are extracted using a series of multi-layer perceptrons (MLPs):

$$f_i = \mathrm{MLP}(p_i)$$

where f_i is the local feature vector for point p_i .

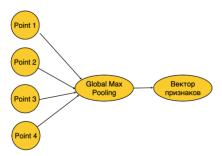

2. Transformation Network (T-Net)

The T-Net learns a transformation matrix T that aligns the point cloud to a canonical space:

$$T = \text{T-Net}(P)$$

where P is the point cloud matrix (each row is a point vector). The transformed point cloud P' is:

$$P' = P \cdot T$$

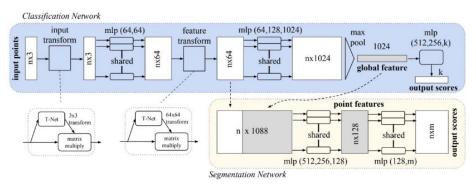

Component	Description
Input	Raw 3D point cloud data (unordered set of points).
Point Feature Extraction	Each point is processed individually to extract local features.
Transformation Network	Learns to align the point cloud to a canonical space using a series of T-Net (Transformation Network) layers.
Symmetric Function (Max Pooling)	Aggregates local features across all points to capture global information. This ensures permutation invariance.
Global Feature Vector	The output of the max pooling operation, representing the global shape information.
Classification Network	Uses the global feature vector to classify the entire point cloud into different categories.
Segmentation Network	Combines local and global features to predict per-point labels for segmentation tasks.
Loss Functions	- Classification Loss: Cross-entropy loss for classification tasks. - Segmentation Loss: Combination of cross-entropy loss and regularization terms for segmentation tasks.
Training	The network is trained using backpropagation and stochastic gradient descent (SGD) with appropriate loss functions.
Inference	Once trained, the network can process new point clouds to perform classification or segmentation tasks.

Agenda

- I. INTRODUCTION
- II. TEMPORAL AND SPATIAL DATA ANALYSIS
- III. CONCLUSION

Using AI in temporal and spatial data analysis is particularly cool for several reasons

1. Pattern Recognition and Anomaly Detection:

- Temporal Data: Al models, especially deep learning techniques like RNNs and LSTMs, excel at recognizing patterns and detecting anomalies in time-series data. This is crucial for applications like predictive maintenance, fraud detection, and stock market analysis.
- Spatial Data: Al can identify complex spatial patterns and relationships, which are often difficult for traditional methods to capture. This is useful in fields like geographic information systems (GIS), urban planning, and environmental monitoring.

2. Scalability and Efficiency:

- Al algorithms can handle large volumes of temporal and spatial data efficiently. Techniques like convolutional neural networks (CNNs) and graph neural networks (GNNs) are designed to process and analyze vast datasets, making them ideal for big data applications.

3. Adaptability and Learning:

- AI models can learn and adapt to new data over time, improving their accuracy and performance. This adaptability is particularly valuable in dynamic environments - AI can model and understand complex relationships between temporal and where data characteristics may change frequently.

4. Integration of Multiple Data Sources:

- Al can integrate and analyze data from multiple sources, including temporal and 10. Innovative Applications: spatial data. This holistic approach allows for more comprehensive and accurate insights, which is beneficial in interdisciplinary fields like climate science, epidemiology, and transportation planning.

5. Predictive Analytics:

- AI models can make accurate predictions based on historical and real-time data. For example, in traffic management, AI can predict congestion patterns and suggest

optimal routes. In healthcare, AI can predict disease outbreaks based on temporal and spatial data.

6. Automated Decision-Making:

- Al can automate decision-making processes by analyzing temporal and spatial data in real-time. This is particularly useful in applications like autonomous vehicles, smart grids, and emergency response systems.

7. Enhanced Visualization:

- Al can enhance data visualization techniques, making it easier to interpret complex temporal and spatial data. Tools like generative adversarial networks (GANs) can create realistic simulations and visualizations, aiding in better understanding and decision-making.

8. Personalization and Customization:

- Al can provide personalized and customized insights based on individual preferences and behaviors. For example, in retail, AI can analyze shopping patterns over time and across different locations to offer personalized recommendations.

9. Complex Relationship Modeling:

spatial variables, which are often non-linear and interdependent. This capability is crucial in fields like economics, ecology, and social sciences.

- Al opens up new possibilities for innovative applications in various domains. For instance, Al-driven drones can analyze spatial data for agricultural monitoring, while Al-powered wearables can track temporal health data for personalized healthcare.
